Abstracts

A biodegradable heart stent, also known as a bioresorbable vascular scaffold (BVS), is a temporary medical implant designed to prop open narrowed or weakened coronary arteries and then gradually dissolve within the body after fulfilling its mechanical support function. Unlike traditional permanent metal stents, these devices are typically fabricated from materials such as polylactic acid (PLA) or other biocompatible polymers that degrade into harmless byproducts like water and carbon dioxide over a predetermined period, usually ranging from several months to a few years. The primary objective of biodegradable stents is to provide temporary scaffolding to prevent acute vessel closure and negative remodeling during the healing process, after which they are metabolized, thereby restoring the artery's natural vasomotion, reducing long-term risks such as late stent thrombosis or permanent foreign body retention, and allowing future treatment options without obstruction.

The global Biodegradable Heart Stent market size was estimated at USD 428.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 9.75% during the forecast period.
