## Abstracts

The 2025 U.S. tariff policies introduce profound uncertainty into the global economic landscape. This report critically examines the implications of recent tariff adjustments and international strategic countermeasures on Bipolar Thyristors competitive dynamics, regional economic interdependencies, and supply chain reconfigurations. In 2024, global bipolar thyristor output was about 21 million units with 25 million units of capacity, the average unit price is about USD 95 and an average gross margin of 35%. Bipolar thyristors are high-power semiconductor switching devices that control large currents and voltages by combining both bipolar transistor and diode characteristics in a four-layer PNPN structure. They operate as latching switches that conduct when triggered and remain on until current falls below a holding threshold, making them vital for AC power control, rectification, and conversion. The supply chain begins with raw materials such as high-purity silicon wafers, dopants (boron, phosphorus), and ceramic substrates; followed by midstream processing including wafer diffusion, photolithography, metallization, and passivation to form the thyristor die. The packaging and assembly phase integrates the die into insulated modules with heat sinks and gate terminals, tested for surge and thermal endurance. Finally, downstream integration supplies power equipment manufacturers for use in HVDC converters, motor drives, inverters, welding equipment, and power grids.

The global Bipolar Thyristors market size was estimated at USD 1940.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.80% during the forecast period.
