Abstracts

Brachytherapy, specifically for breast cancer, is a form of internal radiation therapy where radioactive sources are placed directly into or adjacent to the tumor bed following lumpectomy, delivering a high dose of radiation to the targeted area while minimizing exposure to surrounding healthy tissues such as the heart and lungs. This technique is primarily utilized as a form of accelerated partial breast irradiation (APBI), offering a condensed treatment schedule compared to whole-breast external beam radiation, making it an attractive option for eligible early-stage breast cancer patients seeking shorter recovery times and reduced side effects. The procedure can be administered using various methods, including interstitial needles, balloon-based systems, or strut-based applicators, with the choice of technology often influenced by tumor characteristics, physician preference, and patient anatomy.

The global Breast Cancer Brachytherapy market size was estimated at USD 425.6 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 5.80% during the forecast period.
