Abstracts

As the main component of the electrified railway traction power supply system, the overhead catenary is an important guarantee for the high-speed and stable operation of trains. The overhead catenary system has no spare parts, many components, and a complex mechanical structure. Its state will continue to change under the influence of natural conditions and train loads. In order to ensure the operation order of EMUs and improve the safety and reliability of the system, it is necessary to use detection and monitoring equipment to monitor the state of the overhead contact network equipment, and through defect diagnosis and analysis, timely mine useful information to provide data support for operation and maintenance, equipment management, and design and construction. The overhead catenary is a device in the power supply system of electrified railways and other subways, providing stable and continuous important power for the electrified railway vehicle system. However, due to the complex working environment of electrified railways, there is often a long period of relatively high-speed movement and high-precision contact relationship between the EMU and the power supply overhead line, so the important factors for the interruption of power supply of the overhead catenary are also different. In order to ensure the continuous, stable and safe operation of electrified railways, the main causes of faults on electrified railways, their types of occurrence and the time patterns of occurrence should be understood, so as to quickly eliminate the faults and formulate reasonable and feasible safety measures.
