Abstracts

The 2025 U.S. tariff policies introduce profound uncertainty into the global economic landscape. This report critically examines the implications of recent tariff adjustments and international strategic countermeasures on Cathodic Electrodeposition Coating competitive dynamics, regional economic interdependencies, and supply chain reconfigurations. Global cathodic electrodeposition coating is expected to reach 1,280.5 Kilotons in 2024, with an average selling price of US\$ 3,314 per ton, a production capacity of 1,423 Kilotons, and a gross profit margin of approximately 33.1%. In the cathodic electrodeposition coating process, the metal workpiece acts as the cathode, attracting positively charged paint particles from the paint solution. Since the workpiece being coated is the cathode rather than the anode, the number of metal ions entering the coating film is greatly reduced, thereby improving the performance of the paint film. As the defects of conventional spraying continue to emerge, electrophoresis has become more and more popular. Electrophoretic coating has also begun to be continuously updated, from anodic electrophoretic paint to cathodic electrophoretic paint, from single-component electrophoretic paint to two-component electrophoretic paint. The development of electrophoretic paint has also promoted the development of electrophoretic coating, so that more products no longer use spraying technology but use electrophoresis. The electrophoretic coating process involves four chemical and physical changes: electrolysis, electrophoresis, electrodeposition and electroosmosis. During the electrophoretic process, charged colloidal particles move to the oppositely charged electrode under the action of a DC electric field and are deposited on the electrode surface to form a coating film. Since electrophoretic coating uses water-soluble or water-dispersible ionic polymers as film-forming materials, almost no harmful solvents are volatilized during the coating process, which is environmentally friendly. Major raw materials include resins, solvents, additives, pigments, and fillers, with the chemical industry being its primary upstream sector. This industry is highly specialized

and competitive, with product costs strongly correlated with crude oil prices. While market supply is ample, prices fluctuate to varying degrees due to fluctuations in crude oil prices. Downstream industries include the automotive industry as well as non-automotive sectors, including construction machinery, motorcycles, hardware, and home appliances. These industries are highly correlated with the macroeconomy and exhibit pronounced cyclical characteristics. International giants hold a strong position in the field of electrophoretic paint, especially automotive OEM coatings. The six major companies, including BASF, PPG, Axalta, Nippon Paint, Kansai Paint, and KCC Corporation, hold a market share of more than 80% in automotive electrophoretic paint, especially in the field of passenger car electrophoretic paint, where they hold a monopoly. Currently, the world is placing significant emphasis on the research, development, and promotion of new coatings to minimize harmful emissions and human toxicity, with a particular emphasis on low-VOC coatings. Electrophoretic paints are evolving from traditional water-based and low-VOC coatings to more stringent, full-process environmental protection and resource-saving requirements. On the one hand, national and local standards for VOC, hazardous chemicals, and emissions control in coatings and paint shops are continuously tightening, driving electrophoretic coating formulations toward higher solids content and lower volatile organic compounds (VOCs). This is also prompting manufacturers to implement green alternatives in formulations, additives, and pre-treatments to meet compliance requirements (China's national and technical standards for VOC control in coatings are constantly being updated). On the other hand, operational carbon and water footprints, wastewater/sludge treatment, and resource utilization have become dual concerns for cost and compliance. Manufacturers and coating plants are introducing more efficient wastewater treatment, electrocoagulation/membrane separation, and mineral-carbon composite curing technologies to reduce pollutant emissions and disposal costs. They are also promoting low-energy curing solutions (such as low-temperature curing or widening the curing window to reduce drying tunnel energy consumption), achieving a transition from simple "emission reduction" to "closed-loop resource utilization" and low-carbon operations and maintenance. Currently, downstream customers in the industry are demanding higher economic efficiency for coating products in order to reduce overall coating costs. To meet these demands, coating manufacturers are continuously exploring methods such as lowering coating baking temperatures, reducing heating loss, improving coating processes, and reducing coating usage during the coating process. Currently, electrophoretic coating companies are seeking to reduce coating baking temperatures to around 140-150°C or even lower by improving formulations, thereby achieving energy savings and reducing consumption. Coatings companies have gradually shifted from a product-oriented to a customer-oriented approach. In the competitive landscape of the coatings market, the key to gaining a competitive

advantage lies in reducing costs while ensuring high quality, and improving performance at the same cost. This has also become a driving force behind the continuous upgrading of coatings products. Key research and development areas for cathodic electrophoretic coatings include improving throwability, enhancing edge protection, enhancing appearance, and reducing coating costs.

The global Cathodic Electrodeposition Coating market size was estimated at USD 4244.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 5.00% during the forecast period.
