Abstracts

A cavity band reject filter is a specialized type of radio frequency (RF) filter designed to attenuate or reject a specific, narrow frequency band while allowing signals at frequencies both above and below that band to pass with minimal loss. It typically consists of one or more resonant cavities—often cylindrical or rectangular metal structures—tuned to the target rejection frequency, where the electromagnetic energy is absorbed or reflected. These filters are characterized by high quality factors (Q factors), enabling sharp rejection notches and steep roll-offs, which make them particularly effective in applications requiring precise frequency suppression, such as eliminating interference from strong unwanted signals or harmonics in communication systems, radar, satellite communications, and test and measurement equipment.

The global Cavity Band Reject Filter market size was estimated at USD 320.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.80% during the forecast period.
