Abstracts

Chrysotile fiber cement boards are composite building materials made from a mixture of cement, water, and chrysotile asbestos fibers. Chrysotile, often referred to as "white asbestos," is a naturally occurring mineral fiber known for its high tensile strength, heat resistance, and chemical stability. In these boards, chrysotile fibers serve as reinforcement, enhancing the material's durability, flexibility, and resistance to cracking, while also providing fireproof and insulating properties. These boards are commonly used in construction for roofing, cladding, partitions, ceilings, and other applications where durability and fire resistance are essential. Compared to traditional asbestos fiber cement boards, chrysotile is often promoted as a "safer" asbestos type due to its serpentine structure, which some studies suggest is less likely to lodge permanently in lung tissue compared to amphibole asbestos fibers. However, health and safety concerns persist, as all forms of asbestos have been linked to respiratory diseases and cancer. While chrysotile fiber cement boards remain in use in some parts of the world, many countries have banned or restricted their production and application due to health risks. In these regions, non-asbestos alternatives have become the standard. Chrysotile fiber cement boards are resistant to weathering, chemicals, and pests, making them suitable for long-term use in harsh environments. The boards are non-combustible and can act as a fire barrier, which is critical for safety in residential and industrial buildings. Chrysotile fiber cement boards are less prone to water absorption compared to some other building materials, ensuring their structural integrity in humid conditions. Due to the relatively low cost of chrysotile, these boards offer an affordable solution for construction needs in low- and middle-income countries. Inhalation of chrysotile fibers during production, installation, or deterioration can lead to serious health conditions, including asbestosis, lung cancer, and mesothelioma. Although proponents argue that chrysotile is less harmful than other forms of asbestos, it remains classified as a Group 1 carcinogen by the International Agency for Research on Cancer.

(IARC).
