### Report Overview

Traditional X-ray tubes are known as thermionic tubes. These tubes employ one or more filaments, similar to an incandescent light bulb, which are often made of tungsten. To produce tube current this filament is heated to in excess of 1000 °C, liberating the electrons needed for X-ray production in a process of Thermionic Emission. This “boiling off” of electrons is very inefficient as the energy is mostly wasted in heating up the filaments. The repetitive heating and cooling of the filament for X-ray exposures is not necessary with a Carbon Nano-tube (CNT) field emitter, which is driven by an applied electric field, not by temperature, and is thus known as a ‘cold cathode.’ Thermionic tubes are also comparatively hard to control since the current in the tube is changed only by changing the temperature of the emitter. In a CNT, the current is exactly and instantaneously controlled by an applied voltage.
