Report Overview

Confocal microscopy offers several advantages over conventional widefield optical microscopy, including the ability to control depth of field, elimination or reduction of background information away from the focal plane (that leads to image degradation), and the capability to collect serial optical sections from thick specimens.

There are three types of confocal microscopes: laser scanning microscopes, which use a sharply focused laser that scans over the sample; spinning disk confocal microscopes, which use a disk with pinholes cut into it that are arranged in the shape of a spiral; and programmable array microscopes (PAM), which work much like the spinning disk microscopes, except that the pinholes in the PAM can be opened and closed by the user. All three types of confocal microscopes result in an image, but the spinning disk and PAM systems produce a much higher frame per second image. However, they do not allow for programmable sampling density, as the laser scanning microscope can.
