## Abstracts

A cross-band repeater is a special type of radio repeater whose core function is to receive signals from one frequency band and forward them to another frequency band. This design breaks the limitation that traditional repeaters only work within the same frequency band and realizes communication bridging between different frequency bands. The cross-band repeater receives signals from a certain frequency band (such as 145 MHz in the VHF band) through an antenna. After amplification, filtering and demodulation, the received signal is converted into a format suitable for forwarding. The processed signal is modulated to another frequency band (such as 435 MHz in the UHF band) and radiated through the transmitting antenna. Cross-band repeaters allow devices in different frequency bands to communicate with each other, expand the communication range, support multi-band device access, and build heterogeneous communication networks.

The global Cross-Band Repeater market size was estimated at USD 556.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.90% during the forecast period.
