Abstracts

Cyclized rubber photoresist is a class of light-sensitive polymers derived from natural or synthetic rubber, which undergoes a chemical cyclization process to enhance its thermal stability, adhesion, and resistance to etching agents; it functions as a negative-tone photoresist in photolithography, where exposure to ultraviolet light cross-links the polymer chains, making the exposed regions insoluble in developers and allowing for the transfer of circuit patterns onto substrates such as silicon wafers in semiconductor and microelectronics fabrication. While its usage has declined in advanced nodes due to limitations in resolution and the dominance of more advanced chemistries like DNQ-Novolac and chemical amplification resists, cyclized rubber photoresist remains relevant in certain niche applications, including printed circuit boards (PCBs), MEMS devices, and older-generation integrated circuits, where its cost-effectiveness, excellent adhesion to various surfaces, and good chemical resistance are valued.

The global Cyclized Rubber Photoresist market size was estimated at USD 85.42 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.65% during the forecast period.
