Report Overview

Deep brain stimulation (DBS) is a neurosurgical procedure involving the implantation of a medical device called a neurostimulator (sometimes referred to as a 'brain pacemaker'), which sends electrical impulses, through implanted electrodes, to specific targets in the brain (brain nuclei) for the treatment of movement and neuropsychiatric disorders. DBS in select brain regions has provided therapeutic benefits for otherwise-treatment-resistant disorders such as Parkinson's disease, essential tremor, dystonia, chronic pain, major depression and obsessive-compulsive disorder (OCD). Despite the long history of DBS, its underlying principles and mechanisms are still not clear. DBS directly changes brain activity in a controlled manner, its effects are reversible (unlike those of lesioning techniques), and it is one of only a few neurosurgical methods that allow blinded studies.

Increasing prevalence of neurological disorders is one of the critical factors driving the growth of this market globally. With more than 450 million people worldwide affected by neurological disorders, such as Alzheimer disease, brain injuries, epilepsy, Parkinson's disease (PD), strokes, peripheral neuropathy, and paralysis, the market for DBS has a positive outlook in the coming years. For instance, PD is a progressive neurological disorder that affects the central nervous system resulting in muscle stiffness and slow movement. Although PD cannot be cured completely with medicines, DBS is preferred as it can be used to improve motor symptoms. Moreover, in cases of neurological injuries that lead to paralysis or disability, DBS can be used to restore movement, reduce tremor and dyskinesia, and improve the quality of life. Furthermore, DBS also helps in improving bladder control, restoring hand grasp, and improving walking in patients. Therefore, the increasing number of neurological disorders will bolster the growth of this market in the coming years.
