### Report Overview

The semiconductor market is not an easy one to navigate. Semiconductor wafer fabricators are under constant pressure to maintain maximum precision in highly complex processes that involve expensive materials, corrosive gases, and extreme temperatures.

For years, semiconductor manufacturers have seen optimization of atomic layer deposition (ALD) processes as critical to the success of their businesses. Essential to these processes are ultrahigh-purity (UHP) valves that are highly engineered to deliver precise doses of gases during the deposition process used to create semiconductor chips. While relatively small components, these valves have a huge impact on the success or failure of the chip-building process.

Diaphragm-sealed valves minimize entrapment areas and facilitate purging with a fully swept flow path to improve system efficiency while providing effective flow shutoff. A variety of sizes, materials, and configurations, including atomic layer deposition, thermal immersion, and springless, meet the system requirements of high-purity and ultrahigh-purity applications.
