Abstracts

A displacement sensor is a linear device belonging to metal induction, whose function is to convert various measured physical quantities into electrical power. In the production process, the measurement of displacement is generally divided into two types: measurement of physical dimensions and mechanical displacement. According to the different forms of the measured variable transformation, displacement sensors can be divided into two types of analogue and digital. An important advantage of digital displacement transducers is that they facilitate the direct transmission of signals into computer systems. Digital displacement sensors are used in industries such as manufacturing, automotive, aerospace, robotics, medical devices, and automation for position control, quality assurance, and process optimization. Many digital displacement sensors use non-contact measurement methods, such as optical, capacitive, inductive, or magnetic technologies, reducing wear and extending sensor lifespan. Sensors are becoming smaller and more compact, allowing for integration into tighter spaces and complex systems. The trend toward Industry 4.0 and smart manufacturing drives the demand for digital displacement sensors that can provide real-time data and contribute to process automation and optimization.

The global Digital Displacement Sensor market size was estimated at USD 2222.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 8.30% during the forecast period.
