Abstracts

A doubly fed wind generator (DFIG) is a type of wind turbine technology where the generator's rotor windings are connected to the grid via a partially-rated power converter, allowing the rotor to operate at variable speeds while the stator is directly connected to the grid. This configuration enables more efficient power capture across a wider range of wind speeds compared to fixed-speed turbines, as it permits control of both active and reactive power, enhancing grid stability and reducing mechanical stress. DFIGs are particularly valued for their ability to provide frequency and voltage regulation, making them well-suited for integration into modern power systems with high renewable penetration. However, they are also susceptible to grid fault ride-through challenges and require sophisticated control systems to manage power quality and protect against voltage dips.

The global Doubly Fed Wind Generator market size was estimated at USD 12345.67 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 8.50% during the forecast period.
