Abstracts

Drug eruptions treatment encompasses a range of therapeutic interventions aimed at managing adverse cutaneous reactions caused by medications, which can vary from mild rashes (e.g., maculopapular exanthems) to severe, life-threatening conditions such as Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN), or drug reaction with eosinophilia and systemic symptoms (DRESS). The primary approach involves immediate discontinuation of the offending drug, symptomatic relief (e.g., antihistamines, topical corticosteroids for mild cases), and systemic therapies (e.g., corticosteroids, immunosuppressants, or intravenous immunoglobulins) for severe reactions, alongside supportive care such as wound management, fluid replacement, and infection prevention. Treatment strategies are highly individualized, depending on the severity, specific clinical presentation, and underlying mechanisms of the reaction, often requiring multidisciplinary collaboration among dermatologists, allergists, and critical care specialists.
