Report Overview:

Electrodialysis (ED) is used in seawater desalination to produce salt, food, pharmaceutical, laboratory and recycling environments and others fields. ED is a Laboratory membrane separation process in which ions are transported through ion-permeable membranes, from one stream to another, under the influence of a voltage potential gradient. Two types of membranes are used: cationic-exchange membranes only allow cations to transport, and anion-exchange membranes only allow anions through. These membranes are impermeable to liquids. A large number of alternating cation and anion-exchange membranes are assembled to form diluate and concentrate compartments in what is known as an electrodialysis stack.

Electrodialysis (ED) is used to transport salt ions from one solution through ion-exchange membranes to another solution under the influence of an applied electric potential difference. This is done in a configuration called an electrodialysis cell. The cell consists of a feed (dilute) compartment and a concentrate (brine) compartment formed by an anion exchange membrane and a cation exchange membrane placed between two electrodes. In almost all practical electrodialysis processes, multiple electrodialysis cells are arranged into a configuration called an electrodialysis with alternating anion and cation exchange membranes forming the multiple electrodialysis cells.

The Global Electrodialysis Equipment Market Size was estimated at USD 365.97 million in 2023 and is projected to reach USD 463.07 million by 2029, exhibiting a CAGR of 4.00% during the forecast period.
