Report Overview

An endobronchial blocker is a medical device used during certain surgical procedures or critical care situations to selectively block one lung's airway while allowing ventilation of the other lung. It is often used in procedures like thoracic surgeries, lung isolation during one-lung ventilation, or to manage conditions where differential lung ventilation is necessary. The endobronchial blocker is typically placed through a bronchoscope and positioned in the main bronchus of the target lung to occlude the airflow to that lung. This allows the healthcare provider to control the ventilation and airflow to each lung independently, optimizing oxygenation and ventilation during the procedure.
