Report Overview

Endobronchial ultrasound (EBUS) is primarily used is diagnosis of the progression of lung cancer, its stages and assessment of further possible spread of the diseases to neighbouring body parts including lymph nodes. Endobronchial ultrasound (EBUS) technique has modernized over the time and enables the pulmonologists to sample tissues as well as fluid obtained from lungs and adjacent lymph nodes to visualize the structure surrounding the tracheobronchial tree. The EBUS and endobronchial ultrasound-assisted transbronchial needle aspiration (EBUS TBNA) are recently developed advanced techniques and show promising results in evaluation of pulmonary nodules, and diagnosis of lung infections. Additionally, endobronchial ultrasound biopsy has applications in identification of various diseases including tuberculosis and chronic pulmonary obstructive disorder that negatively impact the lungs and other respiratory organs. For instance, enlarged lymph nodes and abnormal development of masses in the chest and many others. Endobronchial ultrasound biopsy is a minimally invasive technique for collection of tissue samples, majorly from lungs.
