Abstracts

Enteric methane mitigation refers to strategies aimed at reducing methane emissions produced during the digestive process of ruminant animals, such as cows, sheep, and goats. These animals emit methane as a byproduct of fermentation in their stomachs, particularly the rumen, where microbes break down fibrous plant material. Methane is a potent greenhouse gas, and enteric emissions are a major source of agricultural greenhouse gases. Mitigation approaches include dietary changes (like adding fats or seaweed), feed additives (such as 3-NOP or probiotics), genetic selection, and improved animal management practices. Reducing enteric methane helps lower the environmental impact of livestock production while maintaining productivity. Currently, the most promising market for methane emission reduction is feed additives. The upstream processes of feed additives for methane mitigation mainly involve the research, development, and production of active compounds that reduce enteric methane emissions in livestock, such as nitrates, essential oils, tannins, probiotics, or synthetic compounds like 3-NOP. This stage includes raw material sourcing, formulation, and manufacturing by chemical, biotechnological, or agricultural companies. The downstream processes encompass the distribution, integration, and application of these additives in livestock feed by feed mills, farmers, and dairy or meat producers. It also includes monitoring efficacy, regulatory compliance, and carbon accounting to measure emission reductions for sustainability reporting or participation in carbon credit schemes.

The global Enteric Methane Mitigation Technology market size was estimated at USD 69.14 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 16.90% during the forecast period.
