Report Overview

Ethernet hubs pass on all the data that is received on one connection to all other connections. This does not require the same level of intelligence that is contained within the other Ethernet devices. Accordingly a hub is often used as a common connection point for devices in a data network. Hubs connect segments of a LAN. An Ethernet hub contains multiple ports so when a packet arrives at one port, it is copied to the other ports so that all segments of the local area network, LAN can see all the data packets. When using a hub, the data packets are passed to each of its ports regardless of where the packet is actually destined. The Ethernet hub is not able to determine to which port a packet should be sent. By passing to every port, this ensures that it will reach its intended destination. This is a simple and effective manner for managing the data, but it does place a lot of traffic on the network because a lot of unnecessary data is placed onto each port. Accordingly it can lead to poor network response times, but for most small data networks, especially those used for home or small office installations this is not a problem.
