Report Overview

Female urinary incontinence is diagnosed as a condition which causes unintentional urination. Urinary incontinence or stress urinary incontinence usually occurs during physical activities such as running, sneezing, coughing, or even during lifting weights as these activities exert pressures on the urinary bladder. Urinary urge and stress incontinence are different from each other, as the former is caused when the bladder muscles are contracted. Stress urinary incontinence affects women more than men and is mostly caused due to weak sphincter muscle, which can lead to social isolation. Female urinary incontinence is of two types: first is urethral hypermobility and secondly due to intrinsic sphincter deficiency. In the case of urethra hypermobility, increasing abdominal pressure changes the position of urethra. On the other hand in intrinsic sphincter the deficiency, the sphincter has lost its ability to seal in intrinsic sphincter deficiency. Women above 60 year of age often suffer from female stress urinary incontinence due to the weakening of their pelvic muscles. Female stress urinary incontinence can also occur during pregnancy, hysterectomy, menopause, chronic disorders such as tuberculosis, congenital diseases, obesity, and anatomical predisposition.
