Report Overview

Most optical networks have many fiber optic couplings, and even small losses at these nodes can cause significant signal loss, leading to data transmission problems. Therefore, precise fiber alignment at the optical coupling point in the network is a prerequisite for accurate and reliable optical data transmission, as it minimizes signal loss before assembling or encapsulating the optical system. The minimum signal loss also means the lowest optical power requirement, which in turn ensures fewer repeaters, lower capital costs, and fewer failure rates. Different types of motion control systems can be used for fiber optic alignment, from simple manual displacement tables suitable for small-scale and R&D applications to fully automatic control systems with high-precision electric displacement tables. Among them, manual displacement table is the simplest and lowest cost motion control system used for precise linear or rotational motion. They are used for research and development and small batch production environments. The linear electric displacement table with a direct reading encoder is the standard displacement table with the highest accuracy. When used with precision motion controllers, they have a 1 nm MIM capability.
