## Abstracts

A fiber optic delay line is a passive optical component designed to introduce a precise and controlled time delay into an optical signal by leveraging the finite speed of light propagation through an optical fiber. It consists of a specific length of optical fiber, often coiled or packaged compactly, where the delay is directly proportional to the fiber length and inversely proportional to the speed of light in the fiber core, which depends on the refractive index of the material. These devices are critical in applications requiring signal synchronization, phase adjustment, or temporal alignment, such as in telecommunications networks for buffering data packets, in radar and electronic warfare systems for signal processing and jamming mitigation, in interferometric sensing for path length matching, and in quantum computing and optical coherence tomography for precise timing control. Key performance parameters include low insertion loss, high stability against environmental factors like temperature and vibration, polarization maintenance (in PM fibers), and minimal dispersion to preserve signal integrity, with designs often tailored to specific wavelengths, delay ranges, and operational environments.

The global Fiber Optic Delay Line market size was estimated at USD 120.45 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 8.50% during the forecast period.
