### Report Overview:

A liquid crystal display, which is the most typical kind of flat panel display (FPD), consists of two sheets of glass (8th generation substrates are 2,200 x 2,500 mm in size) separated by a 5 μm gap containing liquid crystals (solid or liquid intermediate material with crystalline properties) through which an image can be projected by applying an electric current to the liquid crystals to control the passage of light. This technology takes advantage of the properties of liquid crystals that enable them to both maintain the same orientation with respect to each other and change orientation when a voltage is applied. A large part of the process of creating a liquid crystal display is the formation of the circuits on the glass substrate.

A FPD test is a test conducted during the flat panel display (FPD) manufacturing process, these tests are aimed to check panel functions and to evaluate the manufacturing processes.

To test panel functions in the array process, an Cell Test is conducted using an Cell Tester and an array prober. This test is intended to test the functionality of the TFT array circuit formed for the panel on the glass substrate and detect any wire breakage or short circuit.

Meanwhile, to test the manufacturing process in the array process for the purpose of checking whether the manufacturing process has succeeded or failed and providing feedback to the previous process, TEG testing is conducted using a DC parametric tester and a TEG prober. ("TEG" stands for test element group, which comprises TFT, capacity element, wire element, and other elements of an array circuit.)
