Report Overview

In the development of packaging of electronics, the main aim is to lower cost, increase the packaging density, and improve the performance by maintaining or improving the reliability of the circuits. The concept of the flip-chip process where the semiconductor chip is assembled face down onto the circuit board is ideal for size considerations because there is no extra area needed for contacting on the sides of the component. The performance in high-frequency applications is superior to other interconnection methods because the length of the connection path is minimized. Flip chip bumping is a vital step in the process. The bump provides the necessary electrical connection between the die and the substrate, provides thermal conduction through the two materials, acts as a spacer to prevent electrical shorts and provides mechanical support.
