Report Overview

A functional Near-Infrared Spectroscopy (fNIRS) system is a non-invasive optical imaging technology used to monitor brain activity by measuring changes in blood oxygenation and blood flow in the cerebral cortex. The system uses near-infrared light, which penetrates the skull and is absorbed by hemoglobin in the blood, allowing it to detect differences in oxygenated and deoxygenated blood. fNIRS systems consist of sources and detectors placed on the scalp, which emit and capture the reflected light, respectively, to produce a map of neural activity. This method is highly valued for its portability, ease of use, and ability to measure brain activity in natural settings, making it suitable for a wide range of applications in cognitive neuroscience, psychology, education, and clinical research. It is particularly advantageous for studying populations that may be difficult to assess with traditional imaging methods, such as infants or individuals with limited mobility??.

The global fNIRS System market size was estimated at USD 166 million in 2023 and is projected to reach USD 431.57 million by 2032, exhibiting a CAGR of 11.20% during the forecast period.
