## Abstracts

A force feed lubricator pump, also known as a pressure feed lubricator pump, is designed to forcibly deliver lubricating oil to various parts of machinery. It plays a vital role in ensuring the smooth operation of mechanical equipment by reducing friction, dissipating heat, and preventing wear and tear of components. For example, in an ariel compressor, it provides oil to the cylinder bore for the piston rings and to the packing case for the piston rod packing seal rings. Many force feed lubricator pumps operate based on the positive displacement principle. For instance, gear pumps, a common type of force feed lubricator pump, consist of two gears that mesh with each other. As the gears rotate, the space between the teeth and the pump casing traps and transports the lubricating oil from the inlet to the outlet. The rotation of the gears creates a pressure difference that forces the oil to move. Some force feed lubricator pumps use a plunger mechanism. A plunger moves back and forth in a cylinder. When the plunger retracts, it draws in lubricating oil through an inlet valve. When the plunger extends, it pushes the oil out through an outlet valve, generating the pressure needed to supply the oil to the lubrication points. Force feed lubrication pumps usually have a one-piece steel pump body, which offers high strength and durability, capable of withstanding high pressures. They are equipped with a hardened steel rocker arm to ensure precise control of the lubricant delivery and to enhance the service life. Many models are equipped with a sight glass with a protective housing, enabling operators to visually check the operation status and the level of lubricant. Precision internal and outlet check valves are installed to prevent the backflow of lubricating oil and ensure the unidirectional flow of oil.

The global Force Feed Lubricator Pump market size was estimated at USD 627.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.20% during the forecast period.
