Report Overview

Forced Circulation (FC) Crystallizer evaporates solvent, thus increasing the supersaturation in the process liquor, and causing crystallization to occur. Most conventional FC units operate under vacuum, or at slight super atmospheric pressure. The Forced Circulation (FC) Crystallizer consists of four basic components: the crystallizer vessel, which provides most of the volume dictated by the residence time requirements, the circulating pump, which provides the mixing energy, the heat exchanger, which supplies energy to the crystallizer (in a typical evaporative crystallization operation), and the vacuum equipment, which handles the vapors generated in the crystallizer. Slurry from the crystallizer vessel is circulated, in plug flow fashion, through the heat exchanger, and returned to the crystallizer vessel again, where its supersaturation is relieved by deposition of material on the crystals present in the slurry. The supersaturation is controlled so as to avoid spontaneous nucleation, by sufficient circulation capacity.

The global Forced Circulation (Fc) Crystallizers market size was estimated at USD 345.6 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 6.45% during the forecast period.
