Report Overview

Forced circulation solar systems are a type of solar water heating system that uses a pump to circulate the water through the collectors and into the storage tank. The pump is used to force the water through the system, which allows for higher flow rates and better heat transfer between the collectors and the storage tank. In a forced circulation system, the collectors are typically mounted on the roof and are connected to a pump and a control unit. The control unit measures the temperature of the water in the collectors and in the storage tank and turns the pump on and off as necessary to maintain the desired temperature. The water in the storage tank is then used to provide hot water for the home or building. One advantage of forced circulation systems is that they are able to operate at higher flow rates, which allows for better heat transfer between the collectors and the storage tank. This can result in higher efficiency and faster heating of the water. Additionally, these systems can be designed to work in colder climates, as the pump is able to circulate the water even when temperatures are below freezing.
