Abstracts

A frequency demodulator is a critical electronic component or subsystem designed to extract the original baseband signal from a frequency-modulated (FM) carrier wave by converting variations in frequency into corresponding variations in amplitude or voltage. It operates on the principle of detecting the instantaneous frequency deviation of the input signal, which is proportional to the modulating signal, and is implemented using various techniques such as phase-locked loops (PLLs), slope detection, or quadrature detection. Essential in applications ranging from radio broadcasting and telecommunications to radar and instrumentation systems, frequency demodulators ensure accurate recovery of information encoded via frequency modulation, maintaining signal integrity and minimizing distortion in the presence of noise.

The global Frequency Demodulator market size was estimated at USD 54.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.25% during the forecast period.
