Report Overview

A fully automatic cabinet sterilizer is a medical device used for disinfecting medical devices and equipment. It aims to kill microorganisms on the surface of instruments and equipment by using a combination of heat, pressure, and moisture, thereby providing a high level of sterilization. A sterilizer is usually a large, cabinet like fully automated device, which means it can be programmed to run a disinfection cycle without manual intervention. The sterilization process usually includes several stages, including pre vacuum, heating, sterilization, and drying. During the pre vacuum stage, air is discharged from the sterilization chamber to generate a vacuum. This helps to ensure that the steam used during the sterilization process can penetrate all areas of the sterilized instruments and equipment. During the heating stage, the sterilization chamber is heated to a high temperature, usually around 121-134 degrees Celsius, to kill microorganisms. During the sterilization stage, steam is introduced into the sterilization chamber to maintain the required high temperature and pressure for sterilization. Finally, during the drying phase, the sterilization room is cooled and dried to remove any residual moisture from the instruments and equipment.
