Abstracts

Functional Near-Infrared Spectroscopy (fNIRS) is a non-invasive imaging technique used to measure brain activity by detecting changes in blood oxygenation and volume in the cerebral cortex. This technique utilizes near-infrared light, which penetrates the skull and is absorbed differently by oxygenated and deoxygenated hemoglobin. By placing sensors on the scalp, fNIRS can capture the hemodynamic responses associated with neural activity, providing insights into brain function during various cognitive tasks. fNIRS is portable, relatively inexpensive, and less restrictive than other neuroimaging methods like fMRI, making it suitable for studying populations that are difficult to assess with traditional imaging techniques, such as infants, elderly individuals, and patients with movement disorders. It is commonly used in cognitive neuroscience, psychology, and clinical research to study brain functions like language, memory, and attention.

The global Functional Near-Infrared Spectroscopy (fNIRS) market size was estimated at USD 184.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 11.20% during the forecast period.
