Abstracts

Genome editing, or genome engineering is a type of genetic engineering in which DNA is inserted, deleted, modified or replaced in the genome of a living organism. In 2018, the common methods for such editing use engineered nucleases, or "molecular scissors". These nucleases create site-specific double-strand breaks (DSBs) at desired locations in the genome. The induced double-strand breaks are repaired through nonhomologous end-joining (NHEJ) or homologous recombination (HR), resulting in targeted mutations. The increasing application of genome engineering in treating chronic ailments and therapeutics will be one of the key factors fueling the growth of genome editing market during the next few years. With the continuous prevalence of infectious and chronic diseases such as hepatitis, tuberculosis, malaria, HIV/AIDS, and others, the application of genome editing in treating these ailments has increased considerably in the recent years. According to CDC, there were about 1.8 million new cases of HIV reported in 2016. Such a rapidly increasing number of HIV cases have led to the researchers to work on new gene-based therapies for reducing morbidity and mortality of HIV-infected patients. Consequently, the rise in prevalence of such ailments will impact the demand for novel therapies equipping several genome editing tools in the forthcoming years.

The global Genome Editing market size was estimated at USD 4284.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 9.30% during the forecast period.
