Report Overview

Hemodialysis is a blood-cleaning treatment that involves the use of a dialysis machine and a specific filter known as an artificial kidney, or dialyzer.

Haemodialysis machines perform extracorporeal dialysis to replace the main activity of the kidneys in patients with impaired renal function, such as those with end-stage renal disease. Haemodialysis attempts to replace the excretory functions of the kidney. The haemodialysis machine performs five basic functions. It mixes the dialysate, monitors the dialysate, pumps the blood and controls administration of anticoagulants, monitors the blood for the presence of air and drip chamber pressure, and monitors the ultrafiltration rate. The single-patient haemodialysis systems can be divided into four major components: the dialysate delivery system, the extracorporeal blood delivery circuit, the dialyser, and control circuit. Haemodialysis machines are used on patients who suffer from acute or chronic impairment in kidney function. These machines are for both hospital use and home dialysis.
