Abstracts

The hair screening drug detector is a device that uses modern scientific and technological means to detect drug components in human hair to preliminarily determine whether the person being tested has used drugs in the recent period of time. This detection method has the advantages of simple operation, rapid results, and convenient sampling (only a small amount of hair, such as about 20 strands), which is very suitable for use in grassroots drug control work. The working principle of the hair screening drug detector is mainly based on new membrane detection technology of antigen-antibody specific immune reaction, such as colloidal gold method, time-resolved fluorescence immunochromatography technology or quantum dot immunochromatography technology. These technologies use strip fiber chromatography materials with fixed detection lines and quality control lines to use the competitive reaction between drug components in the test liquid and labeled antibodies or antigens to determine whether there are drug components in the hair. When the analyte binds to the labeled antibody, it competes with the coated antigen for binding sites, and finally the result is determined by observing the color change or fluorescence signal on the detection line.

The global Hair Initial Screening Drug Detector market size was estimated at USD 302.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 3.70% during the forecast period.
