Abstracts

Hard X-ray Photoemission Spectroscopy (HAXPES) is a technique that uses high-energy X-rays (typically in the 5-10 keV range) as an excitation source. By measuring the energy and number of photoelectrons ejected from a sample under hard X-ray irradiation, HAXPES can obtain information about the elemental composition, chemical state and electronic structure of the sample surface and subsurface region. Because the photoelectrons produced by hard X-ray excitation have a larger inelastic mean free path, HAXPES is able to extend the detection depth of conventional XPS (usually less than 10 nm) to nearly 30 nm, enabling deeper nondestructive analysis of the sample. HAXPES has been widely used in materials science, physics, chemistry and other fields, such as non-destructive detection of metal oxide interface layer in semiconductor devices and in situ analysis of electronic structure of solid-liquid interface.

The global Hard X Ray Photoemission Spectroscopy market size was estimated at USD 300.34 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.20% during the forecast period.
