Report Overview:

Hemodialysis is a life-saving intervention for patients with end-stage renal disease (ESRD). Patients with renal disease are affected by progressive loss in the liver functioning. It eventually becomes necessary for the patient to opt for dialysis treatment to sustain healthy life. ESRD is generally the end stage of chronic kidney disease (CKD), which has high prevalence worldwide. Hemodialysis is an alternative for numerous vital functions of kidneys. The dialysis machine itself is termed to be as an artificial kidney. It is generally used for removal of excess content of water and waste products or impurities from kidneys to filter patient's blood when kidneys are damaged or dysfunctional. The dialysis machine brings about filtration of blood using a dialyzer, while removal of the blood (containing impurities or waste products) and returning of the filtered blood to the patient is brought about by surgical vascular access.
