Abstracts

Haemophilia is a group of inherited genetic disorders which causes abnormal or exaggerated bleeding. It impairs the normal mechanism of blood clotting after an injury. Internal bleeding inside the joint or inside brain is commonly seen in the patients with severe to moderate haemophilia. Its symptoms include bleeding from any site of the body. Internal bleeding is fatal as internal bleeding inside the joint causes joint damage and inside the brain, causes brain damage and seizures. The disease is inherited in an X-linked recessive genetic pattern, therefore males are commonly affected with haemophilia while females are usually carriers of the disease. Haemophilia A is caused by the deficiency of clotting Factor VIII, whereas haemophilia B is caused by the deficiency of Factor IX. It is also known as Christmas disease. The disease management includes factor replacement therapy. Factor replacement therapy is the infusion of factor VIII and IX concentrates through injection to control bleeding. These factor concentrates come from two sources i.e. from human plasma or from genetically engineered cell line made by recombinant DNA technology.
