Abstracts

High - density cellular glass is a type of porous inorganic non - metallic material. It is made from waste flat - glass and glass bottles. Through a high - temperature foaming process, the glass raw materials are mixed with a foaming agent and then heated to a high temperature. As the temperature rises, the foaming agent decomposes and releases gas, causing the glass to foam and form a large number of uniform and independent closed - cell pores. The density of high - density cellular glass is generally in the range of 250 - 350 kg/m³. Due to its higher density, it has better mechanical properties, such as higher compressive strength and flexural strength, which enable it to withstand greater pressure and load. It also has excellent thermal insulation properties, with a low thermal conductivity that can effectively prevent heat transfer. In addition, it has good fire - resistance, water - resistance, corrosion - resistance, non - flammability, non - toxicity, non - aging, and no radioactivity. It is widely used in building insulation, especially in non - load - bearing enclosing structures of buildings, as well as in some industrial fields that require high - strength and high - temperature - resistant insulation materials.

The global High-Density Cellular Glass market size was estimated at USD 300.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 7.20% during the forecast period.
