Abstracts

Hybrid Passivated Dual-Junction Cells are advanced photovoltaic devices designed to improve the efficiency of solar energy conversion. These cells combine two key technologies: dual-junction architecture and hybrid passivation techniques.

- 1. Dual-Junction Architecture:** - Dual-junction solar cells consist of two different semiconductor layers (junctions) stacked on top of each other. Each layer is tuned to absorb different parts of the solar spectrum. For instance, the top layer may efficiently absorb high-energy photons (blue light), while the bottom layer captures lower-energy photons (red light). This configuration allows for greater overall efficiency compared to single-junction cells, as it can utilize a wider range of the solar spectrum.
- 2. Hybrid Passivation:** - Passivation is a process that involves reducing surface recombination losses, which occur when charge carriers (electrons and holes) recombine at the surface of the semiconductor instead of contributing to the electric current. Hybrid passivation techniques combine various materials and methods to effectively minimize these losses. - These techniques might involve using different materials (like silicon dioxide or silicon nitride) and optimizing layer structures to improve both electronic properties and light absorption.
- 3. Benefits:** - **Higher Efficiency:** By optimizing different layers for specific photon energies and reducing losses at the surface, hybrid passivated dual-junction cells can achieve higher conversion efficiencies than traditional solar cells. - **Better Performance in Various Conditions:** These cells can be designed to perform better under a range of light conditions, potentially improving energy output throughout the day.

The global Hybrid Passivated Dual-Junction Cell market size was estimated at USD 9281.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 9.20% during the forecast period.
