Abstracts

Hydraulic fracturing is a well stimulation technique in which rock is fractured by a pressurized liquid. The process involves the high-pressure injection of "fracking fluid" (primarily water, containing sand or other proppants suspended with the aid of thickening agents) into a wellbore to create cracks in the deep-rock formations through which natural gas, petroleum, and brine will flow more freely. When the hydraulic pressure is removed from the well, small grains of hydraulic fracturing proppants (either sand or aluminium oxide) hold the fractures open.China is expected to exponentially increase its shale gas production by 2018, which in turn is expected to drive the hydraulic fracturing market in the Asian region. Other countries are also expected to drive their shale gas production in the future to enhance their economic growth.

The global Hydraulic Fracturing market size was estimated at USD 73370.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 6.70% during the forecast period.
