Abstracts

At present, hydrogen circulation systems mainly use hydrogen circulation pumps and ejectors, and both are used simultaneously. In terms of its working principle, the hydrogen circulation pump adopts a motor frequency conversion control motor, which enables the reflux capacity to respond according to different powers, effectively improving hydrogen circulation and high flexibility, but requires additional electricity to maintain its operation. The ejector does not require additional power consumption and has a simple structure, making it reliable and long-lasting. However, its reflux capacity is fixed, so it can only be effective within a certain output power range. The hydrogen circulation components mainly include hydrogen circulation pumps and ejectors, each with its own advantages and disadvantages in practical use. The main advantages of hydrogen circulation pumps are active adjustability, fast response, and wide working range, but they have problems such as complex structure, high noise, parasitic power consumption, and high cost. Injector is a pure mechanical component based on the Venturi effect, which uses the pressure difference caused by high-speed injection of working fluid to suck in and then discharge the injected fluid. The ejector has a simple structure, low noise, high reliability, and no parasitic power, but its injection range is limited, especially difficult to work under low cell density of the fuel cell. In the past few years, the market recognition of ejectors has further increased in practical applications. The mainstream forms of hydrogen circulation in the current market include single/double ejector schemes, hydrogen circulation pump schemes, "hybrid" hydrogen supply schemes integrating circulation pumps and ejectors, and flow bypass and ejector combination schemes. Each scheme has its own advantages and disadvantages. The integrated solution of circulating pump and ejector has obvious advantages in power coverage and efficiency, which is more in line with the current trend of high power and the demand for high product efficiency in the current stage of industrial development. In addition, the previously commonly used single ejector technology route in the market

has now been adopted by multiple companies, and dual ejectors are expected to be mass-produced in 2023. With the development of new hydrogen circulation system technology solutions and the increasing demand for hydrogen circulation systems downstream, it is expected that the market demand for hydrogen circulation pumps and ejectors will continue to increase, and the market size will continue to expand.

The global Hydrogen Circulation Pump and Ejector market size was estimated at USD 136.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 38.20% during the forecast period.
