Report Overview

Immunoabsorption columns have been widely employed for the purification of specific antibodies and antigens. In immunoabsorption columns, plasma is removed by apheresis and passed on through an adsorption medium to remove harmful antibodies, following which it is re-infused into the patient.

Immunoabsorption columns are increasingly being recognised as a promising and low-risk therapy option in a variety of cardiac, haematological, neurological and various other disorders. Immunoabsorption columns are also being increasingly recognised as a useful therapeutic option for various chronic and acute disorders such as multiple sclerosis, Guillain-Barre, myasthenia gravis, chronic inflammatory demyelinating polyneuropathy and autoimmune encephalitis. Using immunoabsorption columns, plasma components are separated by adsorber systems that are designed to selectively bind immunoglobulins. The preservation of plasma proteins, such as coagulation factors, albumin and lower shift of blood volumes, during a procedure is one of the advantages of immunoabsorption columns over other conventional techniques such as plasma exchange.

Various different adsorbers, such as tryptophan, protein A or polyclonal sheep antibodies, can be used alone with immunoabsorption columns. Immunoabsorption columns with protein A or sheep antibodies enable more selective removal of immunoglobulins as well as regenerating mechanisms. Most of the modern immunoabsorption columns contain 2 columns that undergo alternating loading and regeneration cycles, which assists in saving time for even larger blood volumes to be processed.
