Abstracts

An indirect stabilization platform is a device used to isolate external disturbances and provide a relatively stable working environment for the stabilized object. The working principle of the indirect stabilization platform is mainly based on inertial devices (such as gyroscopes) to measure the disturbances of the carrier and convert these disturbances to the stabilization platform through coordinate transformation. Then, a feedforward control method is adopted to control the output of the force opposite to the disturbance through the processor, so as to achieve the purpose of stable control. Specifically, when the carrier is disturbed by the outside world, the gyroscope will sense the disturbance and generate a corresponding signal. After processing, this signal will control the actuator (such as the torque motor) on the stabilization platform to generate a force opposite to the disturbance, thereby offsetting the disturbance and maintaining the stability of the platform.

The global Indirect Stabilized Platform market size was estimated at USD 523.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.50% during the forecast period.
