Report Overview

Industrial sapphire is created by melting aluminum oxide (Al_2O_3) at 2040°C and then encouraging crystal growth with a seed and careful control of the environment. Growers have developed several unique methods for growth, with varying levels of resultant quality, size, and cost. The EFG or Stephanov methods allow the directed growth of shapes like ribbon, or even tubes, however there are many limitations to what can be done. The Czochralski, HEM, or Kriepolous methods allow the highest optical quality sapphire, but the result is a rod like “blob” of crystal called a boule, that must be entirely machined into usable shapes and sizes. The unique properties of sapphire make it an ideal material for a variety of industrial applications. It is strong and durable, yet also lightweight and heat resistant. Additionally, sapphire is optically clear, making it perfect for applications where light transmission is important. These properties make sapphire an ideal choice for products that need to withstand extreme conditions or high temperatures.
