Abstracts

Internal radiation therapy, clinically referred to as brachytherapy, is a highly targeted form of cancer treatment that involves the placement of radioactive sources in the form of seeds, wires, capsules, or other sealed implants directly into or adjacent to a tumor site, delivering a concentrated dose of radiation to cancerous cells while minimizing exposure to surrounding healthy tissues. This technique is distinguished from external beam radiation therapy by its precision and ability to administer higher radiation doses over shorter treatment durations, making it particularly effective for localized cancers such as prostate, cervical, breast, and certain head and neck malignancies. The procedure can be temporary, where radioactive material is inserted for a specific period and then removed, or permanent, involving the implantation of low-dose radioactive seeds that gradually lose their potency. Advancements in imaging guidance, such as MRI and ultrasound, along with sophisticated treatment planning software, have enhanced the accuracy, customization, and safety profile of brachytherapy, solidifying its role as a critical modality within multidisciplinary cancer care protocols.

The global Internal Radiation Therapy market size was estimated at USD 5580.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 6.15% during the forecast period.
