Report Overview

In urinary catheterization a latex, polyurethane, or silicone tube known as a urinary catheter is inserted into a patient's bladder via the urethra. Catheterization allows the patient's urine to drain freely from the bladder for collection. It may be used to inject liquids used for treatment or diagnosis of bladder conditions. The catheter may be a permanent one (indwelling catheter), or an intermittent catheter removed after each catheterization.

Indwelling urinary catheter is retained by means of a balloon at the tip that is inflated with sterile water. The balloons typically come in two different sizes: 5 cm³ and 30 cm³. They are commonly made in silicone rubber or natural rubber. Intermittent catheterisation (IC) is a standard method for bladder emptying. The technique is safe and effective and results in improved kidney and upper urinary tract status, lessening of vesicoureteral reflux and amelioration of continence. In addition to the clinical benefits, patient quality of life is enhanced by the increased independence and security offered by self-catheterization.
