Report Overview

Internet Protocol Version 6 (IPv6) is the most recent version of the Internet Protocol (IP) that is used to identify and locate devices on a network and route traffic across the Internet. It was developed to address the limitations of its predecessor, IPv4, particularly the exhaustion of available IP addresses. IPv6 uses a 128-bit address, providing a vastly larger pool of IP addresses—around 340 undecillion addresses—compared to the 32-bit addressing used by IPv4. This expanded addressing system supports the growing number of internet-connected devices, ensures better routing efficiency, and enhances security features. IPv6 also simplifies network configuration and management, improves network performance, and enables better quality of service (QoS) for data transmission.

This report provides a deep insight into the global Internet Protocol Version 6 (IPv6) market covering all its essential aspects.
