Abstracts

Intramuscular drug delivery refers to the administration of medication directly into the muscle tissue, typically via injection, enabling efficient absorption of drugs into the bloodstream through the rich vascular network of muscles. This method is particularly suitable for substances that are poorly absorbed orally, require rapid systemic effect, or need sustained release, such as vaccines, hormones, antibiotics, and certain biologics. The technique involves careful selection of injection sites—commonly the deltoid, vastus lateralis, or gluteal muscles—to optimize drug bioavailability and minimize discomfort or complications. Its advantages include faster onset of action compared to subcutaneous routes, avoidance of first-pass metabolism, and the ability to deliver larger volumes of medication than subcutaneous injections, making it a versatile and widely utilized approach in both clinical and therapeutic settings.

The global Intramuscular Drug Delivery market size was estimated at USD 3580.42 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 7.80% during the forecast period.
